

Biology notes - Chapter 4

How plants make food

Plants catch sunlight with chlorophyll in their leaves.

In photosynthesis, light, water and carbon dioxide become sugar and oxygen. The sugar feeds the plant; the oxygen is released into the air.

Where it happens: inside chloroplasts, mostly in the leaf's palisade cells, close to the light.

Why it matters: photosynthesis is the start of almost every food chain, and it keeps the air breathable.

Remember for the test:

Without light there is no photosynthesis, so leaves turn to face the sun.
